L97 ANSWER 18 OF 102 MEDLINE on STN DUPLICATE 12
AB A new approach for the regeneration of adenosine triphosphate (ATP) during cell-free protein synthesis was developed to prolong the synthesis and also to avoid the accumulation of inorganic phosphate. This approach was demonstrated in a batch system derived from Escherichia coli. Contrary to the conventional methods in which exogenous energy sources contain high-energy phosphate bonds, the new system was designed to generate continuously the required high-energy phosphate bonds within the reaction mixture, thereby recycling the phosphate released during protein synthesis. If allowed to accumulate, phosphate inhibits protein synthesis, most likely by reducing the concentration of free magnesium ion. Pediococcus sp. pyruvate oxidase, when introduced in the reaction mixture along with thiamine pyrophosphate (TPP) and flavin adenine dinucleotide (FAD), catalyzed the generation of acetyl phosphate from pyruvate and inorganic phosphate. Acetyl kinase, already present with sufficient activity in Escherichia coli S30 extract, then catalyzed the regeneration of ATP. Oxygen is required for the generation of acetyl phosphate and the H(2)O(2) produced as a byproduct is sufficiently degraded by endogenous catalase activity. Through the continuous supply of chemical energy, and also through the prevention of inorganic phosphate accumulation, the duration of protein synthesis is extended up to 2 h. Protein accumulation levels also increase. The synthesis of human lymphotoxin receives greater benefit than than that of chloramphenicol acetyl transferase, because the former is more sensitive to phosphate inhibition. Finally, through repeated addition of pyruvate and amino acids during the reaction period, protein synthesis continued for 6 h in the new system, resulting in a final yield of 0.7 mg/mL.

L97 ANSWER 50 OF 102 BIOSIS on STN
AB An RNA-DNA hybridization assay was used to quantitate the ribonucleoside diphosphate reductase mRNA synthesis (nrd mRNA) to show the gene expression was dependent on protein synthesis. The increased nrd mRNA synthesis induced by inhibition of DNA synthesis was eliminated by simultaneous inhibition of protein synthesis. Protein synthesis is required not only initially but continuously during DNA inhibition for increased expression of nrd mRNA synthesis.

L97 ANSWER 51 OF 102 BIOSIS on STN DUPLICATE 26
AB The requirements for in vitro mitochondrial protein synthesis were studied using isolated mitochondria from cultured adrenal Y-1 tumor cells from mice. Sodium dodecyl sulfate(SDS)-polyacrylamide gel electrophoresis and autoradiography were used to evaluate the translation products. With the optimized system, 1-3% of added [35S]methionine was incorporated. The products of mitochondrial protein synthesis range from 70,000 to 5000 MW. Major autoradiographic bands were observed at 38,000, 31,000, 23,000, 20,000 and 5600 MW; 20-30 protein products of various molecular weights were discernible. Mitochondrial concentrations of 0.8-1.4 mg/ml of incubation gave the better incorporation of [35S]methionine per milligram of protein. Total [35S]methionine incorporation was greatest at 25° C after 90 min. Chloramphenicol inhibited mitochondrial protein synthesis. Cycloheximide had no effect on incorporation at less than 1.0 mg/ml. Mg and ATP in a molar ratio of 1:1 at 5 mM gave optimal incorporation. Other energy generating systems using oxidative phosphorylation to supply ATP for protein synthesis were not as effective as ATP and 5 mM phosphoenol pyruvate, 20 μg/ml pyruvate kinase and 5 mM α-ketoglutarate. No enhancement of in vitro adrenal cell mitochondrial protein synthesis was found with GTP or its analogs.

N,N-bis(2-hydroxyethyl)glycine, N-(tris(hydroxymethyl)methyl)glycine, and N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid were superior to Tris-HCl for mitochondrial protein synthesis. Optimal pH for [35S]methionine incorporation was pH 7.0-7.6. Potassium at 50-90 mM gave the best incorporation of [35S]methionine, and the higher molecular weight products of translation were enhanced at these concentrations. Na and Ca inhibited mitochondrial protein synthesis. Phosphate reduced the amount of mitochondrial protein synthesis. Limited methionine did affect the total amount of protein synthesized, but it had little or no effect on the distribution of label into the different proteins. The maximum rate of incorporation was 20 pmol at 100 μM methionine/mg of mitochondria at 40 min of incubation. Optimal concentrations for the other 18 amino acids were at 30 μg/ml with lesser concentrations reducing the labeled methionine incorporation as well as altering the pattern of proteins synthesized. For osmolarity control, mannitol was superior to sucrose and exhibited an optimal range of 40 to 100 mM. Bovine serum albumin was judged to be nonessential. Many other compounds which were studied had either no effect or were inhibitory to mitochondrial protein synthesis.

L97 ANSWER 55 OF 102 BIOSIS COPYRIGHT (c) 2007 The Thomson Corporation on STN DUPLICATE 28

AB The study of gel-filtered rabbit reticulocyte lysates and lysates which have been passed through 2'5'ADP-Sepharose columns showed that the presence of a sugar phosphate and a reducing system is necessary to maintain maximum rates of protein synthesis and to prevent an early inhibition. The inhibition is due to a reduced rate of initiation of translation and a decrease in the level of methionyl-tRNAf·40S-ribosomal-subunit complexes. Sugar phosphates and reducing agents act co-operatively to prevent these changes: the absence of either sugar phosphates or reducing agents leads to a decrease in polysomes and in methionyl-tRNA·40S-subunit complexes. The requirements for reducing power can be satisfied by either dithiothreitol or by an NADPH-generating system together with a functional thioredoxin/thioredoxin reductase system; evidence is presented to show that these are required for the reduction of S-S bonds. Incubation of lysates in the absence of a suitable reducing system leads to S-S bond formation in a limited number of proteins present in the lysate, but no S-S bonds could be detected in initiation factor eIF-2, the protein which catalyzes the formation of methionyl-tRNA·40S-subunit complexes. When these lysates were incubated under conditions in which protein synthesis is inhibited, eIF-2 was phosphorylated in the smallest of its 3 polypeptide chains (eIF-2α). The phosphorylation of eIF-2α is controlled by the presence or absence of a suitable reducing system but not by sugar phosphates; it appears to be caused by activation of a protein kinase rather than through regulation of the rate of dephosphorylation of this protein. Sugar phosphates probably do not control the phosphorylation of eIF-2 but play some role as an activating cofactor affecting the rate of initiation of protein synthesis. The presence of a suitable reducing system is required to prevent or reverse S-S bond formation in some critical protein(s) in the lysate; the oxidation of SH groups in this protein leads to activation of an eIF-2 kinase and hence to inhibition of initiation.

L97 ANSWER 56 OF 102 BIOSIS COPYRIGHT (c) 2007 The Thomson Corporation on STN DUPLICATE 29

AB Rabbit reticulocyte lysates were passed through 2'5'ADP-Sepharose columns under conditions in which the gel-filtration effect was negligible and low-molecular-weight compounds were retained in the flow-through lysate. Glucose-6-phosphate dehydrogenase [EC 1.1.1.49], 6-phosphogluconate dehydrogenase [EC 1.1.1.44] and glutathione reductase [EC 1.6.4.2] were quantitatively adsorbed by the column and removed from the lysate, but isocitrate dehydrogenase [EC 1.1.1.42] and thioredoxin reductase were retained in the flow-through lysate. The initial rate of protein synthesis in lysates treated in this way was normal, but synthesis stopped

after about 20 min of incubation. This shut-off could be prevented by the addition of dithiothreitol or by providing a means of NADPH generation, which could be achieved either by adding isocitrate or glucose-6-phosphate dehydrogenase. Further experiments used lysates which were first gel-filtered to remove low-molecular-weight metabolites and then passed through 2'5'ADP-Sepharose columns. Under these conditions thioredoxin reductase was efficiently adsorbed by the affinity column, in addition to the 3 enzymes already listed. The maintenance of full protein synthesis activity in these lysates required the addition of both a sugar phosphate and a reducing agent. The sugar phosphate requirement could be satisfied by G-6-P, or 2-deoxyglucose 6-phosphate, or fructose 1,6-bisphosphate, but not by 6-phosphogluconic acid. The requirement for reducing agent could be met by the addition of dithiothreitol, or by an NADPH-generating system together with rabbit thioredoxin reductase. Purified thioredoxin reductase from Escherichia coli was also effective provided E. coli thioredoxin was also added, but the addition of glutathione with glutathione reductase did not activate protein synthesis. There is a dual requirement for the maintenance of high rates of protein synthesis in reticulocyte lysates: certain sugar phosphates must be present, in addition to an NADPH-generating system and a functional thioredoxin/thioredoxin reductase system.

L97 ANSWER 57 OF 102 BIOSIS COPYRIGHT (c) 2007 The Thomson Corporation on STN DUPLICATE 30

AB When rabbit reticulocyte lysates were gel-filtered on Sephadex G-25 or G-50, the rate of protein synthesis in the gel-filtered lysate was the same as in the parent lysate provided appropriate concentrations of ATP, GTP and spermidine or spermine were added. The polyamines increased the rate of synthesis and lowered the Mg2+ optimum. Although gel-filtered lysates prepared in this way synthesize protein at a high initial rate, this rate is maintained for only about 20 min, after which it declines rapidly to a very low rate, even though optimal concentrations of hemin are present. This shut-off was completely prevented by the addition of low concentrations of sugar phosphates capable of acting as NADPH generators: G-6-P, 2-deoxyglucose 6-phosphate, ribulose 5-phosphate and ribose 5-phosphate. Although the addition of isocitrate resulted in the generation of NADPH, the stimulation of protein synthesis was normally less than was achieved with G-6-P. Dithiothreitol also promoted only partial activation, as did fructose 1,6-bisphosphate, a sugar phosphate which does not generate NADPH in this system. Full stimulation was observed, however, when both fructose 1,6-bisphosphate and either dithiothreitol or isocitrate were added. It is argued that the maintenance of maximum rates of protein synthesis in gel-filtered lysates requires the presence of both a sugar phosphate and a reducing agent, which can be dithiothreitol or an NADPH-generating system. Low concentrations of thioredoxin were required for the stimulatory effect of NADPH-generating systems, but not for stimulation by dithiothreitol. A recommended procedure is given for the preparation of highly active gel-filtered lysates and gel-filtered nuclease-treated lysates.

L97 ANSWER 70 OF 102 MEDLINE on STN DUPLICATE 33

AB Inorganic phosphate inhibited the biosynthesis of the macrolide antibiotic turimycin in different strains of Streptomyces hygroscopicus. In the wild type strain a depression was observed with increasing phosphate concentrations. A total inhibition was found at 0.1 M phosphate. In a high producing mutant a minimum of turimycin production occured when the phosphate concentration was between 5 mM and 10 mM. Above this concentration the antibiotic synthesis increased again but the production period shifted to a later period of cultivation. Addition of inorganic phosphate resulted in an initial increase of intracellular cyclic AMP content. But a second elevation characterizing the normal level of cyclic AMP throughout the growth phase was prevented by phosphate. Exogenous cyclic AMP as well as positive effectors of the adenylyl cyclase system were able to overcome the phosphate suppression. Cyclic AMP abolished the

```
     reduction of protein synthesis following
     phosphate addition and caused the reappearance of a protein band
     which may be responsible for the turimycin biosynthesis.

L134 ANSWER 31 OF 31 HCAPLUS COPYRIGHT 2007 ACS on STN
AB X-radiation (2000 r.) applied to the Jensen rat sarcoma in vivo reduced the uptake of P32 into the deoxyribonucleic acid fraction. X-radiation did not reduce the uptake of P32 into the ribonucleic acid fraction, nor did it reduce the uptake of methionine into proteins;

2,4-dinitrophenol, Na pyrophosphate, and adenyl pyrophosphate reduce the uptake of P32 into both nucleic acid fractions and reduce the uptake of methionine into the ribonucleoprotein and the heat-coagulable protein fractions.

L139 ANSWER 2 OF 3 HCAPLUS COPYRIGHT 2007 ACS on STN
AB The present invention relates to polypeptide targets for pathogenic bacteria. Reliable, high throughput methods are developed to identify, express, and purify a number of antimicrobial targets from Staphylococcus aureus, Escherichia coli, Streptococcus pneumoniae, Enterococcus faecalis, Helicobacter pylori, and Pseudomonas aeruginosa. The invention also provides bioinformatic, biochem. and biophys. characteristics of those polypeptides, in particular characterization by mass spectrometry, NMR spectrometry, and x-ray crystallog.
